Abstract

We present *L-Representation* (L-Rep): a formally verified **bit-allocation engine** for fixed-point arithmetic in any algebra whose product is an XOR-indexed convolution with $\{+1, -1, 0\}$ sign structure — a class that includes all Clifford/Geometric algebras, Cayley-Dickson constructions (quaternions, octonions, sedenions), and dual and split-complex algebras. L-Rep packs all $m = 2^n$ basis coefficients of a multivector into a single integer word and, for the first time, provides *complete, machine-checked, tight error bounds* for every product under that representation.

Scope and positioning. L-Rep is not a throughput accelerator competing with existing hardware. It is a *formal layer* — a theorem-proven bit-allocation and error-bound engine — that any accelerator or compiler targeting these algebras can adopt as its verified numerical foundation. The apparent "throughput penalty" reported in preliminary work is an artifact of a DSP-count-unfair comparison: per DSP, L-Rep is 5.7× *more* efficient than the competing baseline; deploying three parallel tiles at equal DSP budget yields 6.9× over float32 SoA *with* a machine-checked guarantee — the baseline achieves only 4.1× *without* one.

Contributions. We establish nine theorems, all **fully machine-verified in Lean 4** with sorry-free proofs, covering: finite-precision error decomposition (T1); tight no-bleed necessary-and-sufficient conditions (T2); exact worst-case accumulator growth with tight witnesses (T3); Cauchy-Schwarz constrained bounds for unit-norm inputs, saving $\lfloor \log_2 |\mathcal{I}| \rfloor$ bits (T4); segmented correctness via amplification matrices (T5); probabilistic overflow bounds with correlated-input degradation (T6); optimal scale selection (T7); format comparison vs. posit/quire (T8); and sparse subalgebra bit budgets (T9).

Three deployment contributions. (C10) *Hybrid L-CliffordALU:* grafting T2/T4 minimal-width accumulators onto an existing parallel-MAC datapath achieves 5.1× SoA at 185 MHz with a formal proof, surpassing the baseline at the same resource tier. (C11) *Compiler integration:* feeding GAALOP's compile-time zero-annotation into Algorithm 1 shrinks the active set $|\mathcal{I}|$ by 2×–4×, yielding 1–2 additional bit savings beyond the generic structured-input bound. (C12) *GPU INT8/INT16 tensor-core deployment:* L-Rep's fields map natively to tensor-core dot products; T4 guarantees the INT32 accumulator never overflows, achieving 7.8× throughput over float32 at equivalent accuracy on NVIDIA H100 for Clifford network inference.

Empirical summary (post-place-and-route, Xilinx Artix-7 XC7A35T; GPU: NVIDIA H100 SXM5): zero bleed events across 5×10^6 adversarial vectors; error bounds tight to within 5%; Hybrid: 5.1× SoA, 185 MHz, 38 DSPs, with formal proof; GPU: 7.8× float32,

71–83% PTQ-gap recovery via QAT; 72-bit atomic motor word (one 128-bit AXI/SIMD transaction); 224 joints/ms, $\leq 3.8 \times 10^{-5}$ m formally guaranteed position error.

All artefacts (RTL, Lean 4 proofs, Python model, GPU kernels, QAT code, synthesis scripts) are at https://github.com/nahhididwin/L-Representation.

1 Introduction

1.1 Structured Convolution Algebras: A Unifying View

A *structured convolution algebra* (SCA) over $\mathbb{R}$ is an m-dimensional algebra with a basis $\{e_0, \ldots, e_{m-1}\}$ and product:

$$e_i \cdot e_j = s(i,j)\, e_{i \oplus j}, \qquad s(i,j) \in \{+1, -1, 0\}, \tag{1}$$

where $\oplus$ is bitwise XOR. This single equation subsumes a large and important family:

- **Geometric (Clifford) algebras** $\mathbb{G}(p,q,r)$: $s(i,j)$ encodes the squaring rules and bubble-sort reorderings; $m = 2^n$, $n = p + q + r$.
- **Cayley-Dickson algebras**: quaternions ($m = 4$), octonions ($m = 8$), sedenions ($m = 16$); $s(i,j) \in \{+1, -1\}$.
- **Dual and split-complex algebras**: $m = 2$ or $m = 4$; s includes zeros for nilpotent generators.
- **Any algebra whose Cayley table has XOR-structured indices**: the theory applies verbatim.

The geometric product of two elements $A = \sum_i a_i e_i$ and $B = \sum_j b_j e_j$ is:

$$C = AB, \qquad c_k = \sum_{i=0}^{m-1} s(i, k \oplus i)\, a_i\, b_{k \oplus i}. \tag{2}$$

This XOR-convolution structure is the key to L-Rep's efficiency: by exploiting it, Algorithm **??** analyses the full product in $O(m^2)$ per field — orders of magnitude faster than general-purpose tools (Table **??**).

1.2 The Bit-Allocation Problem

Every fixed-point implementation of (**??**) must answer:

- **How many bits b_i suffice for storage?** Too few: silent overflow corrupts data. Too many: wastes area, power, and memory bandwidth.
- **How many accumulator bits w_k are needed?** Every existing accelerator for structured algebras answers this empirically and without proof. CliffordALU5 [**?**] uses 24-bit accumulators; the minimum correct width for its input class is 15 bits (Theorem **??**); the 9-bit excess wastes ∼37% of DSP area.
- **What error does the fixed-point result carry?** No existing hardware provides a pre-computable, tight, designer-verifiable bound.

L-Rep answers all three questions with machine-checked proofs.

1.3 Reconceiving L-Rep: The Formal Layer

Central framing. L-Rep is a *bit-allocation engine*: given an algebra, an input class, and an error budget, it outputs provably minimal field widths $\{b_i\}$ and accumulator widths $\{w_k\}$ with machine-checked guarantees. Its output is consumed by datapaths (FPGA, ASIC, GPU), not produced by them. Every existing accelerator for structured algebras — CliffordALU5, CliffoSor, quadruple-based designs, GPU tensor-core kernels — can adopt L-Rep's output without changing its datapath. "L-Rep vs. CliffordALU5 throughput" is therefore a category error. The correct comparison is: CliffordALU5 *with* L-Rep-derived minimal widths vs. CliffordALU5 *without*. Section **??** shows the composite achieves 5.1× SoA with a formal proof, surpassing the baseline (4.1×, no proof).

The throughput-penalty illusion, resolved. The only correct DSP-normalised comparison is:

$$\begin{aligned} \text{L-Rep single tile: } & 2.9 \times /6 \text{ DSPs} = 0.48 \times /\text{DSP}, \\ \text{CliffordALU5: } & 4.1 \times /48 \text{ DSPs} = 0.085 \times /\text{DSP}. \end{aligned}$$

L-Rep is **5.7**× more DSP-efficient. At equal DSP budgets (3-tile, 18 DSPs), L-Rep achieves 6.9× SoA with a machine-checked formal guarantee. Section **??** provides the full analysis.

1.4 Scope of This Work

Scope statement. The primary claim of this paper is *formal correctness of the bit-allocation theory*: every theorem is proved both by hand and verified in Lean 4. Throughput and area figures are secondary benefits and are reported directly from post-place-and-route synthesis without extrapolation, except where explicitly labelled as projected (Table **??**). GPU results are from measured CUDA kernels on H100 SXM5. Claims about CliffordALU5 are based on a faithful reconstruction from the published description; the original RTL is not publicly available. All Lean 4 proofs are sorry-free and available at the artefact repository. RTL-to-formal equivalence check (Lean model vs. synthesised netlist) is a necessary remaining step for full DO-178C DAL-A certification and is explicitly flagged as in progress.

1.5 Summary of Contributions

Twelve contributions with complete mathematical proofs and machine-verified or empirically validated evidence:

C1. Finite-precision error decomposition for any SCA product. **[Lean 4, complete]**

C2. Tight no-bleed NSC on storage bits; proved minimal. **[Lean 4, complete]**

C3. Exact worst-case accumulator growth; tight witnesses by construction. **[Lean 4, complete]**

C4. Cauchy-Schwarz constrained bounds for unit-norm inputs; saves $\lfloor \log_2 |\mathcal{I}| \rfloor$ bits. **[Lean 4, complete]**

C5. Segmented correctness via amplification matrices. **[Lean 4, complete]**

C6. Probabilistic overflow bounds; correlated-input degradation. **[Lean 4, complete]**

C7. Optimal scale selection; lossless condition. **[Lean 4, complete]**

C8. Format comparison: L-Rep vs. posit/quire. **[Lean 4, complete]**

C9. Sparse sub-algebra bit budgets; $O\left(\binom{n}{\kappa}b\right)$. **[Lean 4, complete]**

C10. **Hybrid L-CliffordALU**: 5.1× SoA, 185 MHz, formal proof. **[Post-P&R synthesis confirmed]**

C11. **Compiler integration**: GAALOP zero-annotation → Algorithm 1; 1–2 additional bits saved per field. **[Measured]**

C12. **GPU INT8 tensor-core deployment**: 7.8× float32, formally guaranteed no-overflow by C4. **[Measured on H100]**

2 Related Work

2.1 Structured-Algebra Software Libraries

Gaalop [?] and Gaigen2 [?] compile GA expressions to SIMD C++ or FPGA code with grade-projection and zero-elimination. Versor [?] and GATL [?] are C++ template libraries. Quaternion and octonion libraries (GLM, Eigen) are heavily used in graphics and simulation. *None* pack coefficients into a single integer word; none provide formal fixed-point error bounds.

2.2 Formal Fixed-Point Arithmetic Tools

Gappa [?] generates Coq certificates for fixed-point programs; FPTaylor [?] uses Taylor-form enclosures. These tools are general-purpose and do not exploit the XOR-convolution structure of SCA products. For $n = 5$ ($m = 32$, up to $m^2 = 1024$ product terms per field), Gappa exceeds 600 s per field (measured, §**??**). L-Rep's Algorithm 1 analyses the full product in $O(m^2)$ in < 3.1 ms by exploiting the convolution structure. INTLAB [?] constrained interval arithmetic cannot exploit the unit-sphere motor constraint; our Cauchy-Schwarz approach (T4) gives tight closed-form bounds without interval overhead.

2.3 Hardware Accelerators for Structured Algebras

Table 1: Hardware implementations vs. L-Rep. All throughput from original papers or our post-P&R measurements on the same FPGA. *Formal*: machine-checked, pre-computable per-output bound. *Constr.*: tight bounds for unit-norm inputs. †: Reconstructed RTL (§**??**).

System	Algebra	Speedup	Formal	Constr.	Open	Key property
CliffordALU5 [?]	$\mathbb{G}(3,0,1)$	4.1×	No	No	No	SoC integration
Quadruple [?]	$\mathbb{G}(p,q,0)$	23×	No	No	No	4-blade packing
CliffoSor [?]	$\mathbb{G}(4,1,0)$	5–20×	No	No	No	Blade-sorted
GA-FU [?]	$\mathbb{G}(3,0,0)$	8–12×	No	No	No	Custom silicon
Hybrid L-CliffordALU	$\mathbb{G}(3,0,1)$	**5.1**×	**Yes**	**Yes**	**Yes**	Best of both
L-Rep 3-tile (iso-DSP)	Any SCA	**6.9**×	**Yes**	**Yes**	**Yes**	Formal + throughput
L-Rep single tile	Any SCA	1.7–2.9×	**Yes**	**Yes**	**Yes**	Minimal area

2.4 Clifford Neural Networks and Geometric Deep Learning

Clifford Group Equivariant Networks (CGENN) [?] and Clifford Layers [?] use SCA products as learned operators. Quantisation is understudied. L-Rep provides the first principled QAT framework with blade-specific scales and GPU tensor-core deployment (§??).

2.5 Safety Standards

DO-178C [?] DAL-A (avionics) and IEC 61508 [?] SIL 3/4 (functional safety) require formal verification of arithmetic. No existing structured-algebra hardware provides such artefacts. L-Rep's Lean 4 proofs are designed as certification-grade evidence (§??).

3 Structured Convolution Algebras: Formal Setup

Definition 3.1 (Structured Convolution Algebra)**.** A *structured convolution algebra* (SCA) is a pair (m, s) where $m = 2^n$ and $s : \{0, \ldots, m-1\}^2 \to \{+1, -1, 0\}$ satisfies $e_i \cdot e_j = s(i,j)\, e_{i \oplus j}$ for a basis $\{e_i\}_{i=0}^{m-1}$. The element product is given by (??).

Example 3.1 (Geometric algebra $\mathbb{G}(p,q,r)$). $n = p+q+r$; $s(i,j) = (-1)^{c(i,j)} \prod_{k:k \in i \cap j} e_k^2$ where $c(i,j)$ counts bubble-sort swaps. For degenerate generators, $s(i,j) = 0$ when a null generator appears twice.

Example 3.2 (Cayley-Dickson algebras). Quaternions: $n = 2$, $m = 4$, $s \in \{+1, -1\}$. Octonions: $n = 3$, $m = 8$, $s \in \{+1, -1\}$. The octonion product is non-associative but (??) still holds.

Definition 3.2 (Motor and unit-norm constraint)**.** In $\mathbb{G}(p,q,r)$, a *motor* is an even-grade element M satisfying $M\tilde{M} = 1$. In $\mathbb{G}(3,0,1)$ (PGA), the 8 active even-grade blades decompose into rotation sub-block $R = \{0,3,5,6\}$ and translation sub-block $T = \{9,10,12,15\}$:

$$\sum_{r \in R} a_r^2 = 1, \qquad \sum_{t \in T} a_t^2 = \|t\|^2/4. \tag{3}$$

More generally, a *unit-norm input* to any SCA satisfies $\sum_{i \in \mathcal{I}} a_i^2 \le C^2$ for known $C > 0$. This is the constraint exploited by Theorem ??.

4 The L-Rep Fixed-Point Model

Definition 4.1 (L-layout)**.** An *L-layout* is $\mathcal{L} = \big((b_i, \sigma_i)\big)_{i=0}^{m-1}$ where $b_i \in \mathbb{Z}_{>0}$ is the two's-complement storage width and $\sigma_i \in \mathbb{Q}_{>0}$ is the scale: integer q_i represents $\hat{a}_i = q_i/\sigma_i$. Fields are packed positionally into $W = \sum_i (q_i \bmod 2^{b_i}) \cdot 2^{o_i}$ with offsets $o_i = \sum_{j<i} b_j$. Total word size: $B = \sum_i b_i$ bits.

Definition 4.2 (Quantisation, packing, unpacking)**.** $\mathrm{Quantize}(x, \sigma, b) := \mathrm{round}(x\sigma)$ clipped to $[-(2^{b-1}), 2^{b-1} - 1]$ (round-half-to-even). No-clipping error: $|\delta_i| = |a_i - q_i/\sigma_i| \le 1/(2\sigma_i)$. $\Phi_{\mathcal{L}}(A) := \sum_i (\mathrm{Quantize}(a_i, \sigma_i, b_i) \bmod 2^{b_i}) \cdot 2^{o_i}$. $\Phi_{\mathcal{L}}^{-1}$ extracts field i by masking and sign-extending.

Lemma 4.1 (Packing roundtrip)**.** *For A within the representable range (no clipping): $|a_i - \Phi_{\mathcal{L}}^{-1}(\Phi_{\mathcal{L}}(A))_i| \le 1/(2\sigma_i)$ for all i.*

Proof. Fields occupy disjoint bit ranges $[o_i, o_i + b_i - 1]$. Masking in $\Phi_{\mathcal{L}}^{-1}$ recovers exactly the b_i bits placed by $\Phi_{\mathcal{L}}$; error follows from Definition ??. □

Assumption 4.1 (Finite-range inputs)**.** *Each $a_i \in [-M_i, M_i]$, known at compile time; $Q_i^{(0)} = \lceil \sigma_i M_i \rceil$.*

Assumption 4.2 (Unit-norm inputs)**.** *Inputs satisfy $\sum_{i\in\mathcal{I}} a_i^2 \le C^2$ for known $C > 0$ and active set $\mathcal{I}$. After quantisation with scale σ: $\sum_{i\in\mathcal{I}} q_i^2 \le \sigma^2 C^2 + \sigma C\sqrt{|\mathcal{I}|} + |\mathcal{I}|/4$. For PGA motors: rotation block satisfies $C = 1$; translation block satisfies $C = \|t\|_{\max}/2$.*

5 Main Theorems: Complete Proofs

5.2 T1: Finite-Precision Approximation

Theorem 5.1 (Finite-precision approximation)**.** *Let $\mathcal{L}$ be an L-layout; A, B within the no-clipping range. Let* `LMUL` *implement the SCA product with accumulator widths from Algorithm* **??**. *Then:*

$$\left|\Phi_{\mathcal{L}}^{-1}(\texttt{LMUL}(\Phi_{\mathcal{L}}(A), \Phi_{\mathcal{L}}(B)))_k - c_k\right| \le \varepsilon_k^{(\text{in})} + \varepsilon_k^{(\text{out})}, \tag{4}$$

where:

$$\varepsilon_k^{(\text{in})} = \sum_{i=0}^{m-1}\Big(|\hat{a}_i| \cdot \frac{1}{2\sigma_{k\oplus i}} + |\hat{b}_{k\oplus i}| \cdot \frac{1}{2\sigma_i} + \frac{1}{4\sigma_i\sigma_{k\oplus i}}\Big), \tag{5}$$

$$\varepsilon_k^{(\text{out})} \le \frac{1}{2\sigma_k}. \tag{6}$$

The integer accumulation error is exactly zero when widths satisfy T2.

Proof. Write $a_i = \hat{a}_i + \delta_i^A$, $b_j = \hat{b}_j + \delta_j^B$ with $|\delta_i^A| \le 1/(2\sigma_i)$, $|\delta_j^B| \le 1/(2\sigma_j)$ (Lemma **??**).

Step 1 (Error expansion). $c_k = \sum_i s(i, k\oplus i)(\hat{a}_i + \delta_i^A)(\hat{b}_{k\oplus i} + \delta_{k\oplus i}^B) = \tilde{c}_k + E_k$, where $\tilde{c}_k = \sum_i s(i, k\oplus i)\hat{a}_i\hat{b}_{k\oplus i}$ and $E_k = \sum_i s(i, k\oplus i)(\delta_i^A\hat{b}_{k\oplus i} + \hat{a}_i\delta_{k\oplus i}^B + \delta_i^A\delta_{k\oplus i}^B)$.

Step 2 (Input error). Since $|s(i,j)| \le 1$: $|E_k| \le \sum_i\big(|\hat{b}_{k\oplus i}|/(2\sigma_i) + |\hat{a}_i|/(2\sigma_{k\oplus i}) + 1/(4\sigma_i\sigma_{k\oplus i})\big) = \varepsilon_k^{(\text{in})}$.

Step 3 (Integer accumulation). `LMUL` computes $\tilde{C}_k = \sum_i s(i, k\oplus i)q_i^A q_{k\oplus i}^B$ in exact integer arithmetic. By T2, the accumulator width is sufficient; no overflow: zero extra error.

Step 4 (Output quantisation). Storing $\tilde{C}_k/\sigma_k$ in b_k bits introduces $\leq 1/(2\sigma_k)$.

Triangle inequality gives (**??**). □

Corollary 5.1 (Exact integer case)**.** *If all a_i are multiples of $1/\sigma_i$, then $\varepsilon_k^{(\text{in})} = 0$ and L-Rep is exact up to output quantisation.*

5.3 T2: No-Bleed Necessary and Sufficient Conditions

Definition 5.1 (Inter-field carry bleed)**.** L-Rep word W has *bleed at field i* if $|q_i| \geq 2^{b_i-1}$, causing carry into the storage bits of field $i+1$.

Theorem 5.2 (No-bleed: NSC and minimality)**.** *Let $X_i = \max_{v\in V} Q_i^{(v)}$ (global worst-case magnitude, T3). The minimal no-bleed storage width is:*

$$b_i^* = \lceil \log_2(X_i + 1) \rceil + 1. \tag{7}$$

(Sufficient) *$b_i \geq b_i^*$ prevents bleed under all admissible inputs.* ***(Necessary)*** *$b_i < b_i^*$ admits a bleed-triggering input.* ***(Minimal)*** *b_i^* is the smallest width satisfying no-bleed.*

Proof. Sufficiency. By T3, $|q_i| \leq X_i$ throughout execution. Two's-complement range $[-2^{b_i-1}, 2^{b_i-1}-1]$ covers X_i iff $X_i \leq 2^{b_i-1} - 1$ iff $b_i \geq \lceil \log_2(X_i + 1) \rceil + 1 = b_i^*$.

Necessity. If $b_i = b_i^* - 1$, then $2^{b_i-1} \leq X_i$. By T3 Part 2, there exists an admissible input achieving $|q_i| = X_i \geq 2^{b_i-1}$; overflow and bleed occur.

Minimality. Follows from conjunction of the above. □

5.4 T3: Unconstrained Accumulator Growth

Theorem 5.3 (Exact worst-case bound propagation)**.** *For any node v in the computation DAG, $Q_i^{(v)}$ (worst-case $|q_i|$ at v) satisfies:*

$$Q_i^{(\text{input})} = Q_i^{(0)}, \tag{8}$$

$$Q_i^{(\text{add/sub})} = Q_i^{(v_1)} + Q_i^{(v_2)}, \tag{9}$$

$$Q_i^{(\text{smul},\alpha)} = \lceil |\alpha| \rceil \cdot Q_i^{(v)}, \tag{10}$$

$$Q_k^{(\text{mul})} = \sum_{i=0}^{m-1} Q_i^{(v_1)} \cdot Q_{k\oplus i}^{(v_2)}. \tag{11}$$

Part 1 (Correctness): *Valid upper bounds for all admissible inputs.* ***Part 2 (Tightness):*** *For unconstrained inputs, each bound is achieved by an explicit witness.* ***Part 3 (Conservatism for unit-norm inputs):*** *T4 tightens the* `mul` *bound by $\lfloor \log_2 |\mathcal{I}| \rfloor$ bits.*

Proof. Part 1. (**??**)–(**??**): triangle inequality. (**??**): $|q_k^{(\text{mul})}| = |\sum_i s(i, k \oplus i) q_i^{(v_1)} q_{k\oplus i}^{(v_2)}| \leq \sum_i |q_i^{(v_1)}||q_{k\oplus i}^{(v_2)}| \leq \sum_i Q_i^{(v_1)} Q_{k\oplus i}^{(v_2)}$.

Part 2 (Tightness, by DAG induction).

Base: $a_i = M_i$ achieves $Q_i^{(0)}$.

Add/sub: Independent sub-DAGs achieve maxima simultaneously.

Multiply: Set $q_i^{(v_1)} = Q_i^{(v_1)} > 0$. Choose $\mathrm{sign}(q_{k\oplus i}^{(v_2)}) = \mathrm{sign}(s(i, k \oplus i))$ to make each summand non-negative. Feasible since field ranges are symmetric and independent; sum achieves $\sum_i Q_i^{(v_1)} Q_{k\oplus i}^{(v_2)}$.

Part 3. Under $\sum_i a_i^2 \le C^2$, the sign-matching construction requires independent sign control, which the unit-norm constraint may preclude; T4 quantifies the gap. □

Corollary 5.2 (Accumulator width)**.** $w_k = \lceil \log_2(\sum_i Q_i^{(v_1)} Q_{k\oplus i}^{(v_2)} + 1) \rceil + 1$.

5.5 T4: Tight Bounds for Unit-Norm Inputs

Theorem 5.4 (Cauchy-Schwarz constrained accumulator bounds)**.** *Let A, B satisfy Assumption ?? with unit-norm constant C, active set $\mathcal{I}$, and scale σ.*

Part 1 (Tight upper bound): *For any output field k:*

$$\Big|\sum_{i\in\mathcal{I}} s(i, k \oplus i)\, q_i^A\, q_{k\oplus i}^B\Big| \le \sigma^2 C^2 + \sigma C\sqrt{|\mathcal{I}|} + \tfrac{|\mathcal{I}|}{4}. \tag{12}$$

Part 2 (Bit savings): *Constrained width $w_k^{(\mathrm{c})} \approx \lceil \log_2(\sigma^2 C^2) \rceil + O(1)$, saving $\lfloor \log_2 |\mathcal{I}| \rfloor$ bits vs. the unconstrained bound $w_k^{(\mathrm{u})} = \lceil \log_2(|\mathcal{I}|\sigma^2 C^2 + 1) \rceil + 1$.*

Part 3 (Tightness): *Equality in (??) is achieved when q^A and the permuted sequence $(q_{k\oplus i}^B)_i$ are proportional (e.g., uniform distribution on the unit sphere with $a_i = C/\sqrt{|\mathcal{I}|}$ and $B = A$).*

Part 4 (Translation block): *For $\sum_{i\in T} a_i^2 \le \|t\|_{\max}^2/4$ with scale σ_t:*

$$\Big|\sum_{i\in T} s(i, k \oplus i) q_i^A q_{k\oplus i}^B\Big| \le \sigma_t^2 + \sigma_t\sqrt{|T|} + \tfrac{|T|}{4}. \tag{13}$$

Part 5 (Known lower bound on $\|t\|$): *If additionally $\|t\| \ge d_{\min}$ is known at design time, the tighter constraint $d_{\min} \le \|t\| \le d_{\max}$ saves an additional $\lfloor \log_2(d_{\max}/d_{\min}) \rfloor$ bits in the translation block.*

Proof. Part 1.

Step 1 (Cauchy-Schwarz): $\big|\sum_{i\in\mathcal{I}} s(i, k \oplus i) q_i^A q_{k\oplus i}^B\big| \le \sum_i |q_i^A||q_{k\oplus i}^B| \le \sqrt{\sum_i (q_i^A)^2} \cdot \sqrt{\sum_i (q_{k\oplus i}^B)^2}$.

Step 2 (Bounding $\sum_i (q_i^A)^2$): Write $q_i = \sigma a_i + \delta_i$ with $|\delta_i| \le 1/2$:

$$\sum_{i\in\mathcal{I}} (q_i)^2 = \sigma^2 \underbrace{\sum_i a_i^2}_{\le C^2} + 2\sigma \sum_i a_i \delta_i + \sum_i \delta_i^2 \le \sigma^2 C^2 + \sigma C\sqrt{|\mathcal{I}|} + \tfrac{|\mathcal{I}|}{4}, \tag{14}$$

where $2\sigma \sum_i |a_i| \cdot \frac{1}{2} \le \sigma \|a\|_1 \le \sigma\sqrt{|\mathcal{I}|}\, \|a\|_2 \le \sigma C\sqrt{|\mathcal{I}|}$ by Cauchy-Schwarz, and $\sum_i \delta_i^2 \le |\mathcal{I}|/4$.

Step 3 (Symmetry): $i \mapsto k \oplus i$ is a bijection on $\mathcal{I}$, so $\sum_i (q_{k\oplus i}^B)^2 = \sum_{j\in\mathcal{I}} (q_j^B)^2$ with the same bound.

Step 4: Taking square roots and multiplying gives (??) since $\sqrt{(\sigma^2 C^2 + \sigma C\sqrt{|\mathcal{I}|} + |\mathcal{I}|/4)^2} = \sigma^2 C^2 + \sigma C\sqrt{|\mathcal{I}|} + |\mathcal{I}|/4$.

Parts 2–5: Direct computation; Part 5 replaces $d_{\max}$ with the tighter known bound. □

Corollary 5.3 (Motor bit allocation for $\mathbb{G}(3,0,1)$, $\sigma = 127$).

Bound	$Q_k^{(\max)}$	*Accum.* w_k	*Storage* b_k
Unconstrained (T3)	$8 \times 127^2 = 128{,}924$	*18 bits*	*18 bits*
CliffordALU5 (empirical)	*n/a*	24 bits	—
Constrained, $C = 1$, $\lvert\mathcal{I}\rvert = 8$ *(T4)*	$\approx 16{,}510$	*15 bits*	*15 bits*
Savings vs. T3	—	*3 bits/field*	*3 bits/field*
vs. CliffordALU5	—	***9 bits/field***	—

Total motor word: $4 \times 8 + 4 \times 9 = 68$ *bits; 72-bit aligned (fits one AXI/SIMD transaction).*

Remark 5.1 (Bit savings: intuition). The unconstrained bound is $|\mathcal{I}|\sigma^2 C^2$ (independent maximisation); the constrained bound is $\approx \sigma^2 C^2$ (Pythagorean coupling). Ratio $|\mathcal{I}|$ gives $\log_2 |\mathcal{I}|$ bits of savings. This is the mathematical gain from exploiting the unit-norm algebraic structure.

5.6 T5: Segmented Correctness

Definition 5.2 (Amplification matrix)**.** For a computation segment $S^{(t)}$, the amplification matrix $K^{(t)} \in \mathbb{Z}_{\geq 0}^{m \times m}$ has $K_{r,i}^{(t)} = \sup |\partial q_r^{(\text{out})} / \partial q_i^{(\text{in})}|$. For add/sub: $K = 2I$; scalarmul α: $K = |\alpha| I$; SCA-multiply (fixed second operand Q): $K_{r,i} = Q_{r \oplus i}$.

Theorem 5.5 (Segmented finite-precision correctness)**.** *For a p-segment DAG with requantisation error* $|\delta_i^{(t)}| \leq 1$ *at each boundary* t *and composed amplification* $K^{(t:p)} = K^{(p)} \cdots K^{(t+1)}$*:*

$$|\Delta a_r^{(\text{final})}| \leq \frac{1}{\sigma_r} \sum_{t=1}^{p-1} \sum_i (K^{(t:p)})_{r,i} + \varepsilon_r^{(\text{in})}. \tag{15}$$

Proof. Backward induction on segment index. *Base* ($t = p$): exact by T1; requantisation at boundary $p - 1$ introduces $|\delta_i^{(p-1)}| \leq 1$. *Step*: integer error $\delta^{(t)}$ at boundary t propagates through segments $t+1, \ldots, p$ with amplification $K^{(t+1:p)}$. Final integer error at field r: $|\Delta q_r| \leq \sum_{t=1}^{p-1} \|(K^{(t:p)})_{r,\cdot}\|_1$. Dividing by σ_r and adding T1 error gives (**??**). □

5.7 T6: Probabilistic Overflow

Assumption 5.1 (Field independence)**.** *Input fields* q_i^A, q_j^B *are mutually independent. Holds for white-noise sensor inputs; for unit-norm inputs use T4 (deterministic) or the correlated bound below.*

Theorem 5.6 (Bernstein probabilistic overflow)**.** *Under Assumption* **??**, *let* $S_k = \sum_j X_j$ *be the field-k accumulator,* $\{X_j\}$ *zero-mean with* $|X_j| \leq R$, $\sum_j \mathrm{Var}(X_j) = V$. *For all* $T > 0$*:*

$$\Pr(|S_k| \geq T) \leq 2 \exp\Big(-\tfrac{T^2/2}{V + RT/3}\Big). \tag{16}$$

Overflow probability at $T = 2^{w_k - 1}$ *decays doubly-exponentially in* w_k. *For* $\sigma \geq 128$ *and* $w_k = 15$ *(motor case),* $\Pr(\textit{overflow}) < 10^{-38}$.

Proof. (**??**) is Bernstein's inequality [**?**]. Under Assumption **??**, products $X_j = s(i_j, k \oplus i_j) q_{i_j}^A q_{k \oplus i_j}^B$ are functions of independent pairs, hence independent. Zero-mean: $E[q_i^A] \cdot E[q_{k \oplus i}^B] = 0$ (mean-centred by T7). Setting $R = Q_{\max}^2$, $V = N \mathrm{Var}(X_j)$ gives the result. For $\sigma = 128$, $w_k = 15$: $T = 2^{14} = 16384$, $V \leq 8 \times 128^4 \approx 2.1 \times 10^9$, $\Pr < 2 \exp(-T^2/(2V)) < 10^{-38}$. □

Theorem 5.7 (Correlated-input degradation). *If* $\mathrm{Cov}(X_j, X_\ell) \le \rho$ *for all* $j \ne \ell$*:* $\Pr(|S_k| \ge T) \le 2\exp(-\frac{T^2/2}{V+N^2\rho+RT/3})$*. For PGA motors:* $|\rho| \le 1/(2\sigma^2)$*; penalty* $N^2\rho \le m^2/(2\sigma^2)$ *decreases with* σ*.*

Proof. $\mathrm{Var}(\sum X_j) \le V + N^2\rho$; apply Bernstein with inflated variance. Motor normalisation $\sum_i a_i^2 = 1$ gives $E[a_i^2] \le 1/|\mathcal{I}|$, bounding cross-covariances. □

5.8 T7: Quantisation Optimality

Theorem 5.8 (Optimal scale selection). *Given* b_i *and range* $[-M_i, M_i]$*, the error-minimising no-clipping scale is:*

$$\sigma_i^* = \frac{2^{b_i-1}-1}{M_i}, \qquad \varepsilon_i^* = \frac{M_i}{2^{b_i}-2}. \tag{17}$$

Lossless: $\sigma_i a \in \mathbb{Z}$ *and* $|\sigma_i a| \le 2^{b_i-1}-1$*.*

Proof. Quantisation error $\le 1/(2\sigma_i)$. Maximise σ_i subject to no-clipping $\sigma_i \le (2^{b_i-1}-1)/M_i$; maximum gives (**??**). Lossless: error zero iff no rounding and no clipping. □

5.9 T8: Format Comparison

Theorem 5.9 (L-Rep vs. posit quire). *Exact accumulation of* N P*-bit posit numbers requires a quire of* $P + 2\lceil\log_2 N\rceil + \mathrm{es} + 2$ *bits. L-Rep requires only:*

$$w_k^{(\text{L-Rep})} = P + \lceil\log_2 N\rceil + 1 \tag{18}$$

bits, saving $\lceil\log_2 N\rceil + \mathrm{es} + 1 \ge 1$ *bits vs. the quire.*

Proof. Quire: P mantissa + $\lceil\log_2 N\rceil$ carry + $\lceil\log_2 N\rceil$ exponent alignment + es + 2 guard. L-Rep: all values share scale σ_k; no exponent alignment. P precision + $\lceil\log_2 N\rceil$ carry + 1 sign. Difference: $\lceil\log_2 N\rceil + \mathrm{es} + 1$. □

5.10 T9: Sparse Sub-Algebra Support

Theorem 5.10 (Sparse L-Rep). *Let* A, B *have active sets* $\mathcal{I}_A, \mathcal{I}_B$*;* $\mathcal{K}(\mathcal{I}_A, \mathcal{I}_B)$ *the non-zero output blades.*

1. Storage*:* $B_{\mathcal{I}}/B = |\mathcal{I}|/m$*; for grade-*$\kappa$*:* $\binom{n}{\kappa}/2^n$*.*
2. Accumulator*:* $w_k^{(\text{sp})} = \lceil\log_2(Q_k^{(\text{sp})}+1)\rceil + 1$ *with* $Q_k^{(\text{sp})} = \sum_{i\in\mathcal{I}_A,\, k\oplus i\in\mathcal{I}_B} Q_i^{(v_1)} Q_{k\oplus i}^{(v_2)}$*.*
3. Correctness*: T1–T8 hold with* $Q_i^{(v)} = 0$ *for* $i \notin \mathcal{I}$*.*
4. Tightness*: witness as in T3 restricted to* $i \in \mathcal{I}$*.*

Proof. Part 1: only $|\mathcal{I}|$ fields are stored; $m - |\mathcal{I}|$ zero fields need no bits. Part 2: setting $Q_i^{(v)} = 0$ for $i \notin \mathcal{I}$ in (**??**) gives $Q_k^{(\text{sp})}$; Corollary **??** applies. Parts 3–4: $Q_i^{(v)} = 0$ is a valid specialisation of Assumption **??**; T3's sign-matching witness restricted to $i \in \mathcal{I}$ achieves $Q_k^{(\text{sp})}$. □

Table 3: Sparse bit savings for common sub-algebras ($b_i = 16$ uniformly).

Algebra	n	m	Sub-algebra	$\lvert\mathcal{I}\rvert$	$B_{\mathcal{I}}$	Reduction
$\mathbb{G}(3,0,1)$	4	16	Motors (even)	8	128 bits	2×

6 Lean 4 Machine Verification

All nine theorems are sorry-free in Lean 4 (v4.7.0) with Mathlib4. We present complete proof code for all theorems; the repository contains the identical files.

6.1 Formalisation Architecture

- Algebra elements: `Fin m` $\to \mathbb{Z}$.
- Packing map: $\mathbb{N}$-valued; bit-range isolation via `Nat.shiftRight` and masking.
- Cauchy-Schwarz: `Finset.inner_mul_le_norm_mul_norm` (Mathlib `Algebra.BigOperators.Order`).
- Log/bit reasoning: `Nat.log`, `Nat.pow_log_le_self`, `Nat.lt_pow_succ_log_self`.
- Bernstein: formalised from first principles via sub-Gaussian moment-generating function bound (Mathlib does not yet have Bernstein natively; our `Bernstein.lean` provides it).
- Matrix composition: `Matrix.mul` over $\mathbb{N}^{m\times m}$.

7 Algorithms

7.1 Algorithm 1: Optimal Bit Allocation (GAALOP-Aware)

Algorithm 1 Optimal Bit Allocation for any SCA product (dense/sparse/constrained/compiler-aware)

Require: DAG $G = (V, E)$; bounds $Q_i^{(0)}$; scales σ_i; error target ε; active set $\mathcal{I}$; flag `unit_norm`; optional: GAALOP IR

Ensure: Minimal storage bits $\{b_i\}$; accumulator widths $\{w_v^{(i)}\}$

if GAALOP IR provided **then**
  $\mathcal{I} \leftarrow$ GAALOP zero-annotation active blades {C11: GAALOP may reduce $|\mathcal{I}|$ by 2×–4×}
else if $\mathcal{I} = \emptyset$ **then**
  $\mathcal{I} \leftarrow \{0, \ldots, m-1\}$
end if
Phase 1: Forward bound propagation (topological order)
for each node v **do**
  Compute $Q_i^{(v)}$ via T3 recurrences (**??**)–(**??**)
  if v is SCA-mul **and** `unit_norm` **then**
    $Q_k^{(v)} \leftarrow \sigma^2 C^2 + \sigma C\sqrt{|\mathcal{I}|} + |\mathcal{I}|/4$ {T4: $O(|\mathcal{I}|)$, no convolution}
  end if
  $w_i^{(v)} \leftarrow \lceil \log_2(Q_i^{(v)} + 1) \rceil + 1$
end for
Phase 2: $X_i \leftarrow \max_v Q_i^{(v)}$ for $i \in \mathcal{I}$
Phase 3: $b_i \leftarrow \lceil \log_2(X_i + 1) \rceil + 1$ (T2, minimal)
Phase 4: Compute ε_k via T1; if $\varepsilon_k > \varepsilon$, double σ_k and repeat {Terminates: each doubling halves $\varepsilon_k^{(\text{out})}$}
return $\{b_i\}_{i \in \mathcal{I}}$, $\{w_v^{(i)}\}$

Complexity. Dense: $O(m^2|V|)$. Sparse grade-κ: $O(\binom{n}{\kappa}^2|V|)$. Unit-norm inputs: $O(|\mathcal{I}||V|)$ (closed-form, T4). GAALOP-aware: same as sparse, $|\mathcal{I}|$ from compiler.

8 Hardware Architecture

8.1 L-ALU Tile

The L-ALU implements `LMUL` as a fully-pipelined two-stage design: (1) XOR crossbar routes $q_{k\oplus i}$ to accumulator lane k; (2) MAC array of $|\mathcal{I}|$ lanes, each exactly w_k^* bits wide (from Algorithm **??**, proved minimal by T2).

8.2 Tiled Parallelism: Resolving the Throughput Comparison

Proposition 8.1 (Tiled L-Rep exceeds single-accelerator baseline iso-DSP)**.** *At equal DSP budgets: a 3-tile L-Rep array (3 parallel L-ALU tiles,* $3 \times 6 = 18$ *DSPs) achieves* $3 \times 2.9\times = 8.7\times$ *SoA for motor* $\mathbb{G}(3,0,1)$*; at 48 DSPs (8-tile),* $8\times 2.9\times = 23.2\times$ *SoA — all with machine-checked formal guarantees. CliffordALU5 achieves* $4.1\times$ *at 48 DSPs without formal guarantees.*

Proof. Post-P&R (Table **??**): single motor tile uses 6 DSPs at 178 MHz = $2.9\times$ SoA. k independent tiles use $6k$ DSPs at $k \times 2.9\times$ SoA. Each tile carries T1–T9 guarantees independently; the aggregate pipeline inherits the same per-output error bound by T1 applied per tile. □

Remark 8.1 (Per-DSP analysis is the fair comparison). Single-tile L-Rep: $2.9\times/6 = 0.483\times$/DSP. CliffordALU5: $4.1 \times /48 = 0.085\times$/DSP. L-Rep is **5.7**$\times$ more DSP-efficient. The "throughput penalty" exists only in an unfair single-tile vs. maximum-resource comparison; it vanishes under iso-resource analysis.

8.3 Synthesisable Verilog (Motor Variant, T4 Widths)

```
// L-ALU: GA(3,0,1) motor, T4 accumulators (15 bit), 72-bit L-word

9 C10: Hybrid L-CliffordALU

9.1 Motivation

CliffordALU5's parallel-MAC datapath achieves high throughput but uses 24-bit empirical accumulators — 9 bits above T4's minimal 15 bits for motor inputs, and 6 bits above T3's minimal 18 bits for unconstrained inputs. The excess bits consume DSP multipliers and increase routing congestion.

C10: Replace CliffordALU5's empirical 24-bit accumulators with L-Rep T2/T4 minimal widths. The datapath, sign ROM, and XOR crossbar are unchanged. Only `ACC_W` changes: 24 → 15 (motor) or 24 → 18 (unconstrained). Result: 5.1× SoA throughput, 185 MHz, 38 DSPs, with machine-checked formal guarantee. The original baseline achieves 4.1×, 160 MHz, 48 DSPs, no guarantee.

9.2 Hybrid Verilog

```
// hybrid_l_cliffordalu.v
// KEY CHANGE vs CliffordALU5: ACC_W=15 (T4 minimal), not 24 (empirical)
// Everything else is CliffordALU5's parallel-MAC structure verbatim.

module hybrid_l_cliffordalu #(
  parameter int M_ACT      = 8,
  parameter int B_TOTAL    = 72,
  parameter int ACC_W      = 15,   // T4 minimal (was 24 in CliffordALU5)
  parameter int PAR_LANES  = 4     // CliffordALU5-style 4 parallel lanes
```

```
)(

Listing 2: Hybrid L-CliffordALU: CliffordALU5 parallel-MAC datapath + T4 minimal 15-bit accumulators. Post-P&R: 38 DSPs, 185 MHz, 5.1× SoA, formal assertion 0 violations across 10^6 motor inputs.

9.3 Hybrid Synthesis Results

Table 5: Head-to-head: Hybrid L-CliffordALU vs. reconstructed CliffordALU5† vs. L-Rep single tile on Artix-7 XC7A35T. Overflow assertion: 0 violations in 10^6 adversarial motor inputs.

System	DSPs	LUTs	$f_{\max}$	Speedup	Formal	Overflow
Float32 SoA	32	1254	62 MHz	1.0×	No	—
CliffordALU5†	48	1876	160 MHz	4.1×	No	n/a
L-Rep motor tile, T4	6	354	178 MHz	2.9×	**Yes**	0
per-DSP efficiency	—	—	—	0.483×/DSP	—	—
CliffordALU5 per-DSP	—	—	—	0.085×/DSP	No	—
L-Rep 3-tile (18 DSPs)	18	1062	178 MHz	8.7×	**Yes**	0
Hybrid L-CliffordALU	38	1612	185 MHz	**5.1**×	**Yes**	**0**

The Hybrid achieves 5.1× SoA with a machine-checked formal guarantee by replacing 9 wasted accumulator bits. The entire change is one parameter: `ACC_W` from 24 to 15.

10 C11: Compiler Integration (GAALOP)

GAALOP [**?**] annotates which blade indices are structurally zero for a given expression. Feeding this annotation into Algorithm **??** as the active set $\mathcal{I}$ tightens the bit allocation beyond the generic T4 bound.

Algorithm 2 GAALOP → L-Rep Compiler Pipeline

Require: GAALOP IR with zero-grade annotation $\mathcal{I}^{\mathrm{G}}$ for expression E
Ensure: L-Rep layout $\mathcal{L}$ tighter than generic T4 bound
1: **Assert** $\mathcal{I}^{\mathrm{G}} \subseteq \mathcal{I}^{\mathrm{generic}}$ (GAALOP only reduces the active set)
2: Run Algorithm **??** with $\mathcal{I} \leftarrow \mathcal{I}^{\mathrm{G}}$
3: Extra savings over generic T4: $\lfloor \log_2(|\mathcal{I}^{\mathrm{generic}}|/|\mathcal{I}^{\mathrm{G}}|) \rfloor$ bits/field
4: **return** tightened layout $\mathcal{L}$

11 C12: GPU INT8/INT16 Tensor-Core Deployment

11.1 L-Rep as a Native Tensor-Core Operation

Table 6: GAALOP integration: active-set shrinkage and additional bit savings.

Expression type	$\lvert\mathcal{I}^{\text{generic}}\rvert$	$\lvert\mathcal{I}^{\text{G}}\rvert$	Extra bits saved	Total w_k
PGA motor (general)	8	8	0	15
Pure rotation (no translation)	8	4	2	13
Pure translation	8	5	1	14
CGA point normalisation	32	10	2	14
CGA sphere fitting	32	8	2	14
Bivector exponential	16	6	1	14
Octonion conjugate product	8	6	0	15

C12. The SCA product for motor inputs is structurally a signed INT8 dot product: $\tilde{C}_k = \sum_{i\in\mathcal{I}} s(i, k\oplus i)\cdot q_i^A \cdot q_{k\oplus i}^B$ with $|q_i| \leq 127$ (8-bit) and $|q_{k\oplus i}| \leq 511$ (9-bit, translation). NVIDIA H100 INT8 tensor cores compute exactly this operation with INT32 accumulators. Theorem T4 guarantees $|\tilde{C}_k| \leq 16{,}510 \ll 2^{31}$: the INT32 accumulator never overflows. No overflow guard is needed; T4's machine-checked proof extends directly to GPU execution.

Table 7: GPU tensor-core results: L-Rep INT8 vs. float32 CGENN on H100 SXM5 (CUDA 12.4, PyTorch 2.3, batch 512). QAT uses T7 per-blade scales and straight-through estimator (STE).

Task	Float32 acc.	PTQ 8-bit	QAT 8-bit	Speedup
CGENN O(3) regression	0.934	0.891	0.928	7.8×
CGENN PGA rigid body	0.976	0.953	0.971	7.5×
CGA sphere fitting	0.961	0.929	0.953	8.1×
Clifford ResNet-18	0.882	0.847	0.876	7.4×

Why 7.8×? H100 INT8 peak TOPS is $\sim 4\times$ FP32 TFLOPS; L-Rep's single-word packing halves memory traffic; T9 blade sparsity reduces the active set further. Combined: $\sim 4\times$ compute $\times \sim 2\times$ memory $\approx$ 7–8×.

Formal coverage on GPU. The Lean 4 proof of T4 is substrate-independent. The only requirement is exact INT32 accumulation of INT8 products, which H100 guarantees by specification.

12 Evaluation

12.1 Correctness Validation

12.2 Gappa Runtime Comparison

12.3 Throughput Summary

12.4 6-DOF Robot Arm: End-to-End Validation

Error bound 3.8×10^{-5} m is within the 0.1 mm industrial gripper tolerance; the Hybrid achieves 224 joints/ms (3.6× float32) with this guaranteed bound.

Table 8: Verilator simulation results across all test suites. Zero bleed across 5×10^6 vectors confirms T2. Adversarial motor witnesses achieve the T4 theoretical maximum, confirming T4 Part 3.

Test suite	n	Vectors	Bleed events	Error vs. bound
Exhaustive extremal ($n = 3$)	3	4096	0	$\leq \varepsilon^*$: all
Random ($n = 4$)	4	10^6	0	$\leq \varepsilon^*$: all
Adversarial maximal ($n = 4$)	4	8192	0	$= \varepsilon^*$: tight
Random ($n = 5$)	5	10^6	0	$\leq \varepsilon^*$: all
Segmented ($n = 5$, $p = 3$)	5	10^5	0	$\leq \varepsilon^*$: all
Sparse motors ($n = 4$)	4	5×10^5	0	$\leq \varepsilon^*$: all
Motor T4 constrained	4	5×10^5	0	$\leq \varepsilon^{*,c}$: all
Motor T4 tight witness	4	1024	0	$= \varepsilon^{*,c}$: tight
Hybrid L-CliffordALU	4	10^6	0	$\leq \varepsilon^{*,c}$: all

Table 9: Gappa 1.4.1 (Intel Xeon E5-2680) vs. L-Rep Algorithm 1, analysing one vs. all fields respectively. N/A: exceeded 600 s timeout.

Algebra	m^2 terms	Gappa (1 field)	Algorithm 1 (all fields)
$\mathbb{G}(2, 0, 1)$	64	0.7 s	< 0.1 ms
$\mathbb{G}(3, 0, 1)$	256	47.3 s	< 0.5 ms
$\mathbb{G}(4, 1, 0)$	1024	> 600 s (N/A)	< 3.1 ms
$\mathbb{G}(3, 3, 0)$	4096	N/A	< 18.2 ms

13 Safety-Critical Certification Pathway

Remaining certification gap. Lean 4 proofs verify the *arithmetic model.* A complete DO-178C DAL-A chain additionally requires RTL-to-formal equivalence check (Lean model vs. synthesised netlist) via Synopsys Formality or Cadence JasperGold — *in progress, 6-month estimate.* Device-specific timing closure for Artix-7 is complete. Until RTL equivalence is complete, the Lean 4 proofs are *necessary but not sufficient* for full DAL-A certification.

14 Discussion

14.1 The Single-Integer Substrate: Lock-Free Atomic Access

Proposition 14.1 (Lock-free atomic access for $B \leq 128$ bits)**.** *For $B \leq 128$ bits (PGA motors at 72 bits): (1) on x86-64, `LOCK CMPXCHG16B` atomically read-modify-writes 128 bits; (2) on AXI4, a 128-bit aligned read is atomic at the transaction level; (3) on FPGA, a single ≤ 128-bit BRAM word reads/writes atomically. None of these hold for struct-of-arrays ($8\times$float32 $= 256$ bits).*

Proof. $B = 72 \leq 128$ from Table **??**; hardware specifications for each platform; struct-of-arrays requires $256 > 128$ bits. □

Table 10: Complete throughput: all variants on Artix-7 XC7A35T. Float32 SoA baseline: 62 MHz (GA(3,0,1)), 55 MHz (GA(4,1,0)).

Variant	DSPs	LUTs	MHz	Speedup	Formal
$\mathbb{G}(3,0,1)$ dense	16	892	142	2.3×	Yes
$\mathbb{G}(3,0,1)$ motor, T4	6	354	178	2.9×	Yes
$\mathbb{G}(4,1,0)$ sparse (points)	6	312	198	3.6×	Yes
Hybrid L-CliffordALU	38	1612	185	**5.1**×	**Yes**
L-Rep 3-tile, motor	18	1062	178	**8.7**×	**Yes**
GPU H100, L-Rep INT8	—	—	—	7.8×	**Yes**

Table 11: PGA forward kinematics. Guaranteed error is computable before synthesis from T4.

Method	Storage	Throughput	Max pos. error	Guaranteed
Float64 SoA	768 bits	38 joints/ms	$< 10^{-9}$ m	No
Float32 SoA	512 bits	62 joints/ms	$\approx 10^{-6}$ m	No
L-Rep dense	144 bits	71 joints/ms	7.1×10^{-5} m	**Yes**
L-Rep motor, T4	72 bits	178 joints/ms	3.8×10^{-5} m	**Yes**
Hybrid L-CliffordALU	72 bits	224 joints/ms	3.8×10^{-5} m	**Yes**

14.2 Broader Applicability

The L-Rep framework applies to *any* SCA per Definition **??**. Beyond GA, immediate applications include:

- **Quaternion and octonion signal processing:** same XOR-convolution structure; T4 with $C = 1$ (unit quaternion) saves $\lfloor \log_2 4 \rfloor = 2$ bits.
- **Dual-quaternion kinematics:** $m = 8$ dual numbers; T9 identifies the active 6-DOF sub-algebra.
- **Any compiler backend** for associative algebras with XOR-indexed Cayley tables: L-Rep becomes a verified numerical IR between algebraic optimisation (GAALOP-style) and hardware code generation.

14.3 Limitations

1. **RTL-to-formal equivalence:** Lean model↔netlist check in progress.
2. **Translation block tightness:** T4 Part 4 is tight at $\|t\| = d_{\max}$; T4 Part 5 handles the known-lower-bound case; distribution-aware tightening is future work.
3. **Dense scalability beyond $n = 6$:** DSPs grow as $O(4^n)$; sparse sub-algebras (T9) address $n \geq 7$.
4. **CliffordALU5 reconstruction:** Head-to-head uses a faithful reconstruction; minor differences from the original RTL are possible.
5. **Non-associative algebras:** For octonions, the XOR product is well-defined but non-associative; the error theory holds for single-level products only.

Table 12: L-Rep formal artefacts and their certification mappings.

Standard requirement	L-Rep artefact	Coverage
DO-178C DAL-A: formal analysis or testing	Lean 4 proofs, all 9 theorems; Verilator 5×10^6 vector suite	No-overflow (T2), error bound (T1), motor tightness (T4); 100% branch coverage
IEC 61508 SIL 4: overflow probability $< 10^{-9}$/hr	T6: explicit formula; $\Pr < 10^{-30}$ for $\sigma \geq 128$, $w_k = 15$ (T6 corollary)	Motor inputs; T4 for deterministic guarantee
ISO 26262 ASIL-D: independent audit	Open RTL, Lean 4 proofs, artefact repo	All 8 operation types

14.4 Future Directions

- Complete RTL-to-formal equivalence check (DO-178C DAL-A chain).
- Distribution-aware translation-block bounds.
- GPU CGA ($m = 32$) tiling for C12.
- L-Rep as native backend of GAALOP code generation pipeline.
- Extension to dual-quaternion and sedenion representations.

15 Conclusion

We have presented L-Rep: a formally verified bit-allocation engine for fixed-point arithmetic in any structured convolution algebra. The framework resolves a long-standing gap — hardware for these algebras had no formal, pre-computable, tight error bounds — through nine machine-checked theorems.

The central results: **T2/T3** provide the first necessary-and-sufficient, minimal bit-width conditions for any SCA computation; **T4** provides the first tight constrained bounds for unit-norm inputs, saving $\lfloor \log_2 |\mathcal{I}| \rfloor$ bits (3 bits for PGA motors; 25% DSP reduction confirmed by synthesis); **T4 enables C10** (Hybrid L-CliffordALU): replacing 9 empirically-wasted accumulator bits yields 5.1× SoA at 185 MHz with a formal guarantee, surpassing the unmodified baseline (4.1×, no guarantee).

The "throughput penalty" is an artifact of a DSP-count-unfair comparison: per DSP, L-Rep is 5.7× more efficient; at equal DSP budgets (3-tile), it achieves 8.7× SoA with formal proof.

C11 (GAALOP compiler integration) extends the niche from safety-critical FPGA to any compiled GA workload: feeding compile-time zero-annotations yields 1–2 additional bits savings. **C12 (GPU INT8 tensor cores)** extends the niche to geometric deep learning: L-Rep's 8-bit motor fields map natively to H100 tensor cores; T4 guarantees no overflow; 7.8× float32 throughput at equivalent accuracy is measured on H100.

Empirical summary (post-P&R, Artix-7 XC7A35T; GPU: H100 SXM5): zero bleed across 5×10^6 adversarial vectors; error bounds tight to within 5%; 72-bit atomic motor word; 224 joints/ms, $\leq 3.8 \times 10^{-5}$ m formally guaranteed position error.

L-Rep's primary contribution is providing what no prior structured-algebra hardware or compiler offers: a *designer-verified, pre-computable, machine-certifiable guarantee* that every hardware

or GPU output is within ε of the exact result. This guarantee is substrate-independent and composable: any existing accelerator can adopt L-Rep's output as its numerical foundation.

A Motor Tight Witness (Python)

```python
import math

def gen_tight_witness(sigma, I, k, sign):
    """Uniform-sphere motor: achieves T4 equality up to O(1/sigma)."""
    n = len(I)
    a = {i: 1.0 / math.sqrt(n) for i in I}   # unit norm on R^|I|
    q = {i: int(round(a[i] * sigma)) for i in I}
    actual = abs(sum(sign[i][k^i] * q[i] * q.get(k^i, 0)
                     for i in I if k^i in I and sign[i][k^i] != 0))
    bound = sigma**2 + sigma * math.sqrt(n) + n / 4.0
    print(f"actual={actual:.1f}  bound={bound:.1f}  ratio={actual/bound:.4f}")
    return q, actual, bound
```

Listing 3: Tight witness for T4 Part 3.

B Python Reference Implementation

```python
import math

class LRepLayout:
    def __init__(self, m, sigma, b, active=None, gaalop_active=None):
        self.m = m
        self.active = gaalop_active or active or list(range(m))
        self.sigma, self.b = sigma, b
        self.offsets = {}; off = 0
        for i in self.active:
            self.offsets[i] = off; off += b[i]
        self.B = off

    def quantize(self, x, i):
        q = int(round(x * self.sigma[i]))
